

Let  $X$  be locally compact. If  $f: X \rightarrow Y$  is continuous, does it follow that  $f(X)$  is locally compact? What if  $f$  is both continuous and open? Justify your answer.

Does not necessarily follow from continuity.

$X = \mathbb{Q}$  with discrete topology, then every ~~subset~~ <sup>finite subset</sup> is open and compact.  $Y = \mathbb{Q}$  with subspace topology from the standard on  $\mathbb{R}$ .

$f = \text{identity}$ .

if  $f$  is continuous then it holds. Let  $U$  be a neighborhood of  $x$ ,  $V$  a compact set containing  $U$  then  $f(U)$  is an open neighborhood of  $f(x)$  and  $f(V)$  is compact containing  $f(U)$ .
